Abstract
Behavior of income and wealth distributions, philanthropic giving appears to follow an approximate power law distribution as measured by the size of gifts received by individual recipients. We explore the ecology of giving by analyzing data sets of individual gifts to a diverse group of institutions dedicated to education, medicine, art, public housing, and religion. We find that the average form of gift size distribution often varies by an extremely consistent factor. Our analysis, we conclude, could be used to detect unusual behavior that diverges from the general distribution. In general, categories, offering a mechanistic explanation for variation in institutional gift size distributions. We discuss how knowledge of gift size distributions may be used to create an institutional gift-giving profile to help in fundraising goals and to design an institution-specific giving program.

Introduction
The power law distribution of philanthropic contributions continues to attract attention in the cultural and economic analysis of a great diversity of social institutions. Beyond 1970 and 2010, there have been two general approaches [1] of one approach is to model the distribution of income in the United States and the other is to model the distribution of income in the United States. The distribution of income in the United States has been found to be a power law distribution [2]. The distribution of income in the United States has been found to be a power law distribution [2]. The distribution of income in the United States has been found to be a power law distribution [2].

Conclusion
The power law distribution of philanthropic contributions continues to attract attention in the cultural and economic analysis of a great diversity of social institutions. Beyond 1970 and 2010, there have been two general approaches [1] of one approach is to model the distribution of income in the United States and the other is to model the distribution of income in the United States. The distribution of income in the United States has been found to be a power law distribution [2].

Deformed Zipf's law in personal donation

Q. Chen, C. Wang and Y. Wang¹
Department of Applied Science, School of Management, Beijing Normal University, Beijing 100875, P.R. China

Abstract
The power law or Zipf's law phenomena in human behavior have been widely observed and received scientific attention. In this letter, we explore an empirical distribution of personal donation. A sample of donation to the victims of Wenchuan earthquake in 2008 demonstrates that human donation has a particular pattern. The upper part is governed by Zipf's law and the lower part exhibits a certain distribution. We propose a deformed model which people's wealth distribution follows power law. They are willing to donate a certain part of their wealth and have preference to some specific amounts. This model provides us not only a reasonable explanation on the reported donation pattern but also an effective method to get access to large-scale personal wealth distribution.

Introduction
The power law distribution or Zipf's law phenomena in human behavior have been widely observed and received scientific attention. In this letter, we explore an empirical distribution of personal donation. A sample of donation to the victims of Wenchuan earthquake in 2008 demonstrates that human donation has a particular pattern. The upper part is governed by Zipf's law and the lower part exhibits a certain distribution. We propose a deformed model which people's wealth distribution follows power law. They are willing to donate a certain part of their wealth and have preference to some specific amounts. This model provides us not only a reasonable explanation on the reported donation pattern but also an effective method to get access to large-scale personal wealth distribution.

Match Criteria

The following criteria will be considered to determine if this alert should be fired.

Amount Sensitivity Scale ⓘ

3.00

The amount sensitivity scale determines how many gifts will trigger the alert based on the amount of the gift. This will most often be used to alert for situations when a gift is larger than expected. Positive numbers will trigger alerts for gifts larger than normal. Negative Values would trigger for gifts smaller than expected (use caution).

Typical Values are shown below.

- 2 (Aggressive) - This would alert when a gift was within 2 times the interquartile range (IQR) from their median gift amount. For a bi-weekly giver with a median gift of \$400 and an IQR of \$65, this alert would be generated if a gift of \$530 was recieved.
- 3 (Normal) - This would alert when a gift was within 3 times the interquartile range (IQR) from their median gift amount. For a bi-weekly giver with a median gift of \$400 and an IQR of \$65, this alert would be generated if a gift of \$595 was recieved.

In the event that there is a very consistent giver—every gift is the exact same amount—we use a fallback value. The fallback amount sensitivity is calculated as 15% of the median gift amount.

Match Criteria

The following criteria will be considered to determine if this alert should be fired.

Amount Sensitivity Scale [i](#)

The amount sensitivity scale determines how many gifts will trigger the alert based on the amount of the gift. This will most often be used to alert for situations when a gift is larger than expected. Positive numbers will trigger alerts for gifts larger than normal. Negative Values would trigger for gifts smaller than expected (use caution).

Typical Values are shown below.

- 2 (Aggressive) - This would alert when a gift was within 2 times the interquartile range (IQR) from their median gift amount. For a bi-weekly giver with a median gift of \$400 and an IQR of \$65, this alert would be generated if a gift of \$530 was recieved.
- 3 (Normal) - This would alert when a gift was within 3 times the interquartile range (IQR) from their median gift amount. For a bi-weekly giver with a median gift of \$400 and an IQR of \$65, this alert would be generated if a gift of \$595 was recieved.

Frequency Sensitivity Scale ?

In the event that there is a very consistent giver—every gift is the exact same amount—we use a fallback value. The fallback amount sensitivity is calculated as 15% of the median gift amount.

The frequency sensitivity scale determines how many gifts will trigger the alert based on the frequency. This will most often be used to alert for situations when a gift would have been expected but not given. Positive numbers would trigger alerts for gifts that are late. Negative Values would trigger for gifts that are early.

Typical Values are shown below.

- 2 (Aggressive) - This would alert when a gift was within 2 standard deviations from their mean. For a bi-weekly giver with a mean of 14 days and a standard deviation of 3.8, this alert would be generated if no gift was received within 22 days since their last gift.
- 3 (Normal) - This would alert when a gift was within 3 standard deviations from their mean. For a bi-weekly giver with a mean of 14 days and a standard deviations of 3.8, this alert would be generated if no gift was received within 26 days since their last gift.

In the event that there is a very consistent giver—every gift is the same number of days apart—we use a fallback value. The fallback frequency sensitivity is calculated as 15% of the average days between gifts. If that value is less than a day, then we again fallback to 3 days.

Saturday

Former Giver

No Contribution in the Last *

375 Days

and

Median Frequency Less Than

320 Days

Former Givers are defined as not having a contribution since the number of days provided and having a median frequency less than the number of days provided. Providing no value for Median Frequency would have the effect of not having it be considered.

Lapsed Giver

No Contribution in the Last *

150 Days

and

Median Frequency Less Than

100 Days

Lapsed Givers are defined as not having contributed since the number of days provided and having a median frequency less than the number of days provided. Providing no value for Median Frequency would have the effect of not having it be considered.

New Giver

Contribution Count Between *

1 to 5

and

First Gift in the Last

150 Days

New Givers are defined as having a total contribution count between the values provided. Their first contribution must also be within the number of days configured.

Occasional Giver

Median Frequency Days *

33 to 94

Occasional Givers are defined as having a median frequency between the days provided. They must also have at least one gift in that timeframe.

Consistent Giver

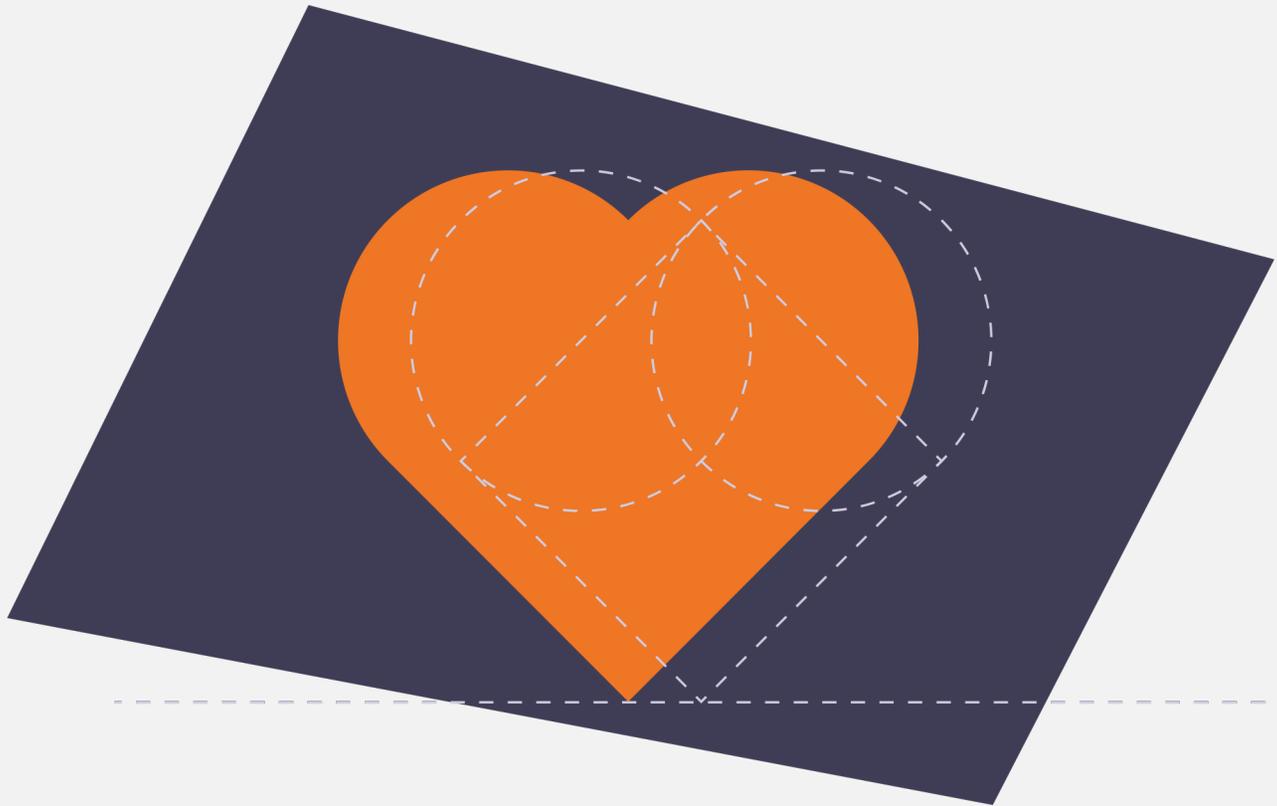

Median Less Than *

32 Days

Consistent Givers are defined as having a median frequency less than the days provided. They must also have at least one gift in that timeframe.

Non-Giver

Non-Givers are defined as having never given.

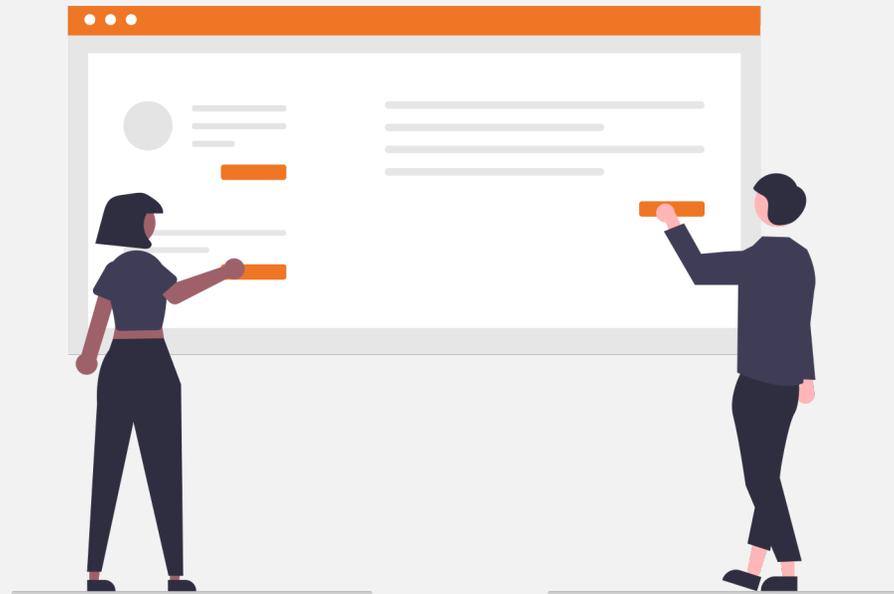

Special Thanks
